

Clean accuracy and corruption sensitivity answer different questions

Exploratory JPEG-95 matched-clean design

$$\Delta E = (AP_{FP8} - AP_{INT8})_{\text{corrupt}} - (AP_{FP8} - AP_{INT8})_{\text{clean}}$$

Report clean fidelity → absolute corrupted AP → interaction and scale → engine runtime

Final VOC/KITTI holdouts

Original-source clean;

six-block means

Clean FP8-INT8 gap

+ 1.60 AP

Corrupted FP8-INT8 gap

+ 1.05 AP

95% paired-image interval: [0.91, 1.16]

Clean-adjusted change

-0.55 AP

95% paired-image interval: [-0.78, -0.29]

Take-home: In these holdouts, FP8 remains more accurate under corruption on average, but part of its clean advantage contracts.

Report clean fidelity → corrupted AP → paired interaction → scale/runtime sensitivity.
